

# **Trifunctional Protein Deficiency (TFP)**

A fatty acid oxidation disorder

## ***What is it?***

Trifunctional Protein Deficiency (also known as TFP) is an inherited fatty acid oxidation disorder. Patients with fatty acid oxidation disorders, like TFP, cannot breakdown fats (long chain fatty acids) to energy. Once the body uses up its primary source of energy (glucose, or blood sugar), the body begins to fail because it cannot then make energy from fats. Therefore, people with TFP must eat on a very regular basis and should not go long without food.

## ***What are the symptoms?***

A person with TFP can appear normal at birth. Symptoms are variable and range from recurrent episodes of hypoglycemia and muscle weakness, to heart, liver, or eye problems. These symptoms can progress very quickly to coma, cardiac arrest, brain damage, or even death in children who are not eating well. In addition, mothers of babies with TFP can have problems such as HELLP syndrome or acute fatty liver of pregnancy. Many symptoms of TFP can be prevented by immediate treatment and lifelong management. People with TFP typically receive follow-up care by a team of professionals that is experienced in treating people with metabolic disorders.

## ***Inheritance and frequency***

TFP is inherited in an autosomal recessive manner. This means that for a person to be affected with TFP, he or she must have inherited two non-working copies of the gene responsible for causing TFP. Usually, both parents of a person affected with an autosomal recessive disorder are unaffected because they are carriers. This means that they have one working copy of the gene, and one non-working copy of the gene. When both parents are carriers, there is a 1 in 4 (or 25%) chance that both parents will pass on the non working copies of their gene, causing the baby to have TFP. Typically, there is no family history of TFP in an affected person. TFP is a rare fatty acid oxidation disorder; the total number of people affected with TFP is not known.

## ***How is it detected?***

TFP can be detected through newborn screening. A recognizable pattern of elevated chemicals alerts the laboratory that a baby may be affected. Confirmation of newborn screening results is required to make a firm diagnosis. This is usually done by a physician that specializes in metabolic conditions, or a primary care physician.

## ***How is it treated?***

TFP is treated by eating frequently and avoiding fasting, and sometimes drinking a special formula and a special medication, as recommended by a genetic metabolic medical professional.
